Received 13 February 1998/Returned for modification 17 March 1998/Accepted 20 April 1998

*Ehrlichia sennetsu* is the causative agent of human Sennetsu ehrlichiosis. Heat shock protein 60 (HSP60) and HSP70 (DnaK) are two major bacterial HSPs, and their interaction modulates the stress response. Previously, we cloned and sequenced *groE* and expressed *groEL* of *E. sennetsu*. HSP60 (GroEL) was immunogenic and cross-reactive in *Ehrlichia* spp. The present study was designed to (i) characterize the HSP70 gene of this organism and (ii) determine whether the expression of these two HSPs is inducible upon exposure to heat stress. A gene encoding an HSP70 homolog was isolated and sequenced from a gene library. The ehrlichial HSP70 gene encoded a 637-amino-acid protein, which had an approximate molecular mass of 68,354 Da and which was homologous to DnaK of *Escherichia coli*. A DNA sequence resembling −35 and −10 promoter sequences of *E. coli* dnaK was observed upstream of the ehrlichial HSP70 gene. Alignment of the predicted amino acid sequence with that of *E. coli* DnaK, *Borrelia* *Borrelia*, *Salmonella*, *Borreliia*, and *Chlamydia* HSP70s showed 63, 67, 63, 62, 58, and 53% identity, respectively. By reverse transcription-PCR analysis, the mRNA levels of ehrlichial HSP70 and HSP60 were examined after temperature shifts from 28 to 37°C and from 37 to 40°C. HSP70 mRNA induction levels were greater than those of HSP60 mRNA after a 37- to 40°C temperature shift, whereas the reverse was true after a 28- to 37°C temperature shift. Our data suggest that HSP60 and HSP70 may play different roles during transfer from vector temperature to human body temperature and during a febrile condition characteristic of ehrlichial disease. This study also provides a useful model system for examining mRNA expression in obligatory intracellular bacteria.

*Ehrlichia sennetsu*, which belongs to the family *Rickettsiaceae*, is an obligate intracellular bacterium of monocytes and macrophages. *E. sennetsu* is the etiologic agent of human Sennetsu ehrlichiosis, a febrile illness with lymphadenopathy, cases of which have occurred in western Japan and recently in Malaysia (10, 28). The term heat shock protein (HSP) refers to the evolutionarily highly conserved stress-inducible or constitutive proteins that maintain homeostasis in eukaryotic and prokaryotic cells (16, 23). The immunology of HSP has been studied extensively. For example, HSP60 (GroEL) and HSP70 (DnaK) of a number of bacteria, including *Mycobacterium*, *Borrelia*, *Chlamydia*, and *Legionella* spp., have been recognized as common antigens in the immune response to bacterial infection and in autoimmune diseases (4, 8, 11, 13, 15, 25, 30, 35). Recent studies have revealed that bacterial HSP60 and HSP70 modulate immunity by directly inducing cytokine mRNA production in macrophages (25). In addition, studies of the prokaryotic cells also revealed that an HSP70 homolog might play a role in the recognition or binding between a pathogen and the host cell, both of which are believed to be critical for *Ehrlichia* infection. To date, these data suggest that HSP70 may be present on the bacterial surface and that the heat shock response appears to mediate adhesion to the host cell (12, 14, 22, 24). It is reported that bacterial HSP70 contributes to the pathogenesis of *Mycobacterium* spp., which infect and replicate in macrophages (25). The role of bacterial HSP70 in *Ehrlichia*-infected macrophages has not been established.

Bacterial HSPs are regulated by heat shock promoters that can be recognized by the σ^32 factor of RNA polymerase holoenzyme. It is reported that *Escherichia coli* and chlamydial HSP70s have −35 promoter regions which are similar to the heat shock promoter of HSP60 (5, 9). Genetic data show that the interaction between HSP60 and HSP70 modulates the heat shock response (7, 20, 22, 33). In a sense, HSP70 plays the role of chaperone by primarily preventing aggregation or premature folding until the substrate protein can assemble into the appropriate multisubunit complex and be translocated across a membrane or passed on to a different chaperone HSP60 (1). It is also believed that HSP70 acts as a negative modulator of the heat shock response via interaction with a σ^32 homolog (21, 22). The interaction between ehrlichial HSPs and host immunity has not been established. In our laboratory, the HSP60 homolog of *E. sennetsu* was characterized, expressed, and immunologically analyzed (34). So far, the HSP60 genes and proteins of several *Ehrlichia* spp. have been characterized (16, 31, 32, 34). Although a DNA sequence of a small fragment of the Dnak gene from *Rickettsia prowazekii* was reported (3), a complete HSP70 base or amino acid sequence has not been reported for any *Rickettsia* or *Ehrlichia* spp.

We have been interested in the role of HSPs in ehrlichial pathogenesis. The present study was designed to examine whether HSP60 and HSP70 expression in *E. sennetsu* is inducible following a temperature shift, which may occur in *Ehrlichia* when it infects a human host. For obligation intracellular bacteria, it is difficult to investigate the heat shock responses of their HSPs at the protein level because purification of the organisms is difficult, purification itself may cause a stress response, and the presence of homologous HSPs in the host cell may not be easy to distinguish. There is no report on HSP70 or HSP60
mRNA expression in *Ehrlichia or Rickettsia* spp. Therefore, we developed a reverse transcription-PCR (RT-PCR) method with the 16S rRNA of *E. sennetsu* as the internal control and investigated the thermodenaturation of HSP60 and HSP70 mRNA. Since the complete HSP70 gene has never been isolated in *Ehrlichia* spp., it was necessary to sequence the HSP70 gene of *E. sennetsu* in order to conduct our experiment. In this study, therefore, the entire HSP70 gene of *E. sennetsu* was cloned and sequenced.

**MATERIALS AND METHODS**

**Bacterial strains, vectors, and reagents.** 16S, phage, Blucscript plasmid, and *E. coli* XL1-blue MRF*®* and SOLR strains were purchased from Stratagene (La Jolla, Calif.). *E. coli* DH5*α* competent cells and restriction enzymes were purchased from GIBCO-BRL (Grand Island, N.Y.).

**Ehrlichial cultivation and purification.** *E. sennetsu* was cultivated in a P388D*®* murine macrophage-like cell line (26). DNA was extracted from the organisms, which had been purified by Sephacryl S-1000 chromatography (27).

**Cloning the partial HSP70 gene from an *E. sennetsu* gene library.** All procedures were carried out by using the λZAPII/CIAP cloning kit (Stratagene), according to the manufacturer’s instructions. Briefly, genomic DNA was prepared by purified *E. sennetsu* by sodium dodecyl sulfate (SDS) lysis, protein extraction and precipitation and digested with the *Xba*I restriction enzyme. The digested fragments were ligated into the *Xba*I site of the λZAPII vector. The gene library was constructed by infecting the *E. coli* XL1-blue MRF*®* strain with recombinant phage. Clones containing ehrlichial antigens were identified by using the rabbit anti-*E. sennetsu* serum (34), which was preabsorbed with *E. coli* lysate and the recombinant HSP60 of *E. sennetsu* (34). This absorbed serum specifically reacted with the 70-kDa protein and some other proteins, but not with the HSP60 of *E. sennetsu*, in Western blotting. The 70-kDa protein is one of the major protein components in a Coomassie blue-stained *E. sennetsu* SDS-polyacrylamide gel electrophoresis gel. When the intact organism was mildly treated with Sarkosyl, this 70-kDa protein appeared to be predominant in the soluble fraction of the organism. We believe that this 70-kDa protein is an HSP70 homolog. A recombinant phleomycin plasmid (pES70X) was excised from the positive λZAPII phage in the presence of helper phage f1 and was used to transform *E. coli* SOLR cells, according to the manufacturer’s instructions. The transformation efficiency of *E. coli* cells was cultured at 37°C overnight in Luria broth (LB) medium containing 50 μg of ampicillin per ml. The phagemids were isolated by an alkaline method (29).

**DNA sequence analysis.** The DNA sequence was determined by the dideoxy-termination method with an Applied Biosystems (Foster City, Calif.) 373A DNA sequencer. The DNA sequence reaction was conducted with suitable synthetic oligonucleotides as primers. Translation of the nucleotide sequence and alignment of the amino acid sequence were performed by using DNA/Genome software (Hitachi Software Engineering Co., Ltd., Yokohama, Japan). Northern analysis was performed using a software basic local alignment search tool (2).

**Southern blot analysis of genomic DNA of *E. sennetsu*.** A restriction enzyme map was constructed based on the base sequence of the cloned partial HSP70 gene. The phagemid (pES70X) containing the HSP70 gene truncated at the 5′ end (32 μg) was digested with restriction enzyme *Xba*I (30 U) at 37°C for 1 h; then the mixture was digested with *EcoR*I (30 U) at 37°C for 2 h. The mixture was adjusted by following the instructions of the manufacturer, and the mixture was incubated at 37°C for an additional 1 h. The reaction mixture was immediately applied to a 1% agarose gel and electrophoresed at 90 mA for about 2 h. A DNA ladder (HindIII-digested λ174 phage; GIBCO-BRL) was used to identify the molecular range of the fragments. An approximately 0.4-kb restriction fragment was recovered from the gel by using a QIAEX II agarose gel extraction kit (Life Technologies, Gaithersburg, Md.). The isolated RNA (2 μg) was heated at 75°C for 5 min and reverse transcribed in a 30-μl reaction mixture containing 1× reaction buffer (50 mM Tris-HCl [pH 8.3], 75 mM KCl, 3 mM MgCl₂, 0.5 mM dNTPs, 1 U of reverse transcriptase (GIBCO-BRL), and 1.5 mM concentrations of primers which were complementary to the sequence of the HSP70 mRNA (5′-TTCACCTCCAATCCATCAACATA-3′) of *E. sennetsu* (34) at 42°C for 1 h. The reaction was terminated by incubating the mixture at 94°C for 2 min. The cDNA product (1 to 2 μl) was amplified in a 50-μl reaction mixture containing 1× PCR buffer (10 mM Tris-HCl [pH 8.3], 50 mM KCl, 1.5 mM MgCl₂), a 0.2 mM deoxynucleotide triphosphate mixture, 2.0 U of Taq DNA polymerase (Life Technologies, Inc.), and 0.4 μM concentrations of 5′ and 3′ primers of 5′-CCAGGGAATGTTGTTGACGTC-3′ and 5′-ACTCTGCTGATGCAGACCATC3′, respectively, based on the *E. sennetsu* HSP70 gene sequence, for the partial *E. sennetsu* HSP70 gene or 5′-ATTGGGTTGTAGCTGATGCAGACCATC-3′ and 5′-CCAGGGAATGTTGTTGACGTC-3′, respectively, based on the *E. sennetsu* HSP60 gene, for the partial *E. sennetsu* groEL gene in a DNA thermal cycler (model 480; The Perkin-Elmer Corp., Norwalk, Conn.). Each PCR cycle was programmed to denature at 94°C for 45 s, annealing at 60°C for 45 s, and extension at 72°C for 2 min and was repeated for 28 cycles. To rule out contamination of DNA during RNA preparation, a negative control was prepared by assembling a reaction mixture that contained RNA and all reagents except for reverse transcriptase. To monitor the influence of ehrlichial growth during the incubation period, and as an internal control, 16S rRNA primers based on the 16S rRNA gene of *E. sennetsu* (5′-AGAAAGACGTGTAAACCTGAC-3′ and 5′-GTATTACCGCGGCGGTGGA-3′) were added to the reaction mixture with HSP70 or HSP60 primers. The different primers made the RT-PCR products distinguishable based on the sizes of their amplified products (approximately 300 bp for HSP70 RNA, 500 bp for HSP60 RNA, and 400 bp for 16S RNA). To make sure that the primers used were not cross-react with the host HSP70 or HSP60 gene, RNA of the uninfected P388D*®* cells was isolated and used as a template as well.

**Determination of relative HSP70 and HSP60 mRNA levels under heat stress.** To compare relative levels of HSP70 and HSP60 mRNA, RT-PCR products were electrophoresed in a 1.7% agarose gel. HindIII-digested dX174 replicative-form DNA fragments (GIBCO-BRL) were used as molecular size markers (72 to 1353 bp). The amount of PCR products was analyzed by using a gel video system (Gel Print 2000; BioPhotronics Corp.; Ann Arbor, Mich.) and image analysis software (ImageQuaNT; Molecular Dynamics, Sunnyvale, Calif.).

**Nucleotide sequence accession numbers.** The nucleotide sequences of the HSP70 genes of *Brucella*, *E. coli*, *Salmonella*, *Borrelia*, *Chlamydia*, and *Mycobacterium* have been assigned GenBank accession number as follows: *Brucella*, M95799; *E. coli*, D10765; *Salmonella*, U58305; *Borrelia*, M97912; *Chlamydia*, M53033; and *Mycobacterium*, M96106. The nucleotide sequence of *E. sennetsu* has been deposited in GenBank accession number as AF060197.
RESULTS

Cloning of the \textit{E. sennetsu} HSP70 gene. An \textit{Xba}I fragment (2.5 kb) of \textit{E. sennetsu} genomic DNA was cloned in \textit{\lambda} phage. The phagemid excised from the recombinant phage was designated pES70X and consisted of a 1.3-kb open reading frame (ORF) at one end of the insert (Fig. 1). The nucleotide sequence of the ORF and the corresponding predicted amino acid sequence indicated that the ORF was the partial HSP70 gene. Based on the restriction enzyme map of the ORF (data not shown), \textit{Xba}I and \textit{Eco}RI sites (at nucleotide positions 701 and 1140, respectively) were used to make an approximately 0.4-kb probe for cloning the 5' end of the \textit{ehrlichial} HSP70 gene (Fig. 1). Southern blot analysis revealed that genomic DNA digestion with \textit{Hin}dIII resulted in a 1.5-kb fragment which contained the 5' end of the HSP70 gene (Fig. 2). The fragment was isolated and ligated into a \textit{Hin}dIII-digested \textit{pBluescript} plasmid, referred to as pES70H. The sequence of the insert indicated that there was 1,342 bp of ORF at one end of the fragment. The nucleotide sequence at the 3' end of the ORF in the pES70H insert overlapped with that of the 5' end of the ORF in the pES70X insert. The overlapped region contained the sequence of the 0.4-kb probe (Fig. 1). These two ORFs represent the full length of the region encoding the \textit{ehrlichial} HSP70 (Fig. 1).

Characterization of the \textit{E. sennetsu} HSP70 gene. The nucleotide sequence of the gene encoding the \textit{E. sennetsu} HSP70 homolog and the predicted amino acid sequence are shown in Fig. 3. A 1,911-bp ORF commences with a methionine codon (ATG) and terminates with a stop codon; it encodes a 637-amino-acid protein with an approximate molecular mass of 68,354 Da. A purine-rich putative ribosome-binding site (Shine-Dalgarno sequence) is located 7 nucleotides ahead of the ATG initial codon. DNA sequences resembling \textit{235} and \textit{210} promoter sequences of \textit{s70} precede the start codon by 55 and 28 bp, respectively (Fig. 3). The \textit{235} promoter region was also similar to the consensus heat shock promoter recognized by \textit{s32}, the \textit{s32} subunit of \textit{E. coli} RNA polymerase (Fig. 3).

ORFs represent the full length of the region encoding the \textit{ehrlichial} HSP70 (Fig. 1).

Characterization of the \textit{E. sennetsu} HSP70 gene. The nucleotide sequence of the gene encoding the \textit{E. sennetsu} HSP70 homolog and the predicted amino acid sequence are shown in Fig. 3. A 1,911-bp ORF commences with a methionine codon (ATG) and terminates with a stop codon; it encodes a 637-amino-acid protein with an approximate molecular mass of 68,354 Da. A purine-rich putative ribosome-binding site (Shine-Dalgarno sequence) is located 7 nucleotides ahead of the ATG initial codon. DNA sequences resembling \textit{235} and \textit{210} promoter sequences of \textit{s70} precede the start codon by 55 and 28 bp, respectively (Fig. 3). The \textit{235} promoter region was also similar to the consensus heat shock promoter recognized by \textit{s32}, the \textit{s32} subunit of \textit{E. coli} RNA polymerase (Fig. 3).

Alignment of the predicted amino acid sequence with the protein sequences of \textit{E. coli} DnaK indicates that the encoded
protein is an HSP70 homolog (Fig. 4). Figure 4 shows that the ehrlichial HSP70 has 67, 63, 62, 58, and 53% identity with that of Brucella, E. coli, Salmonella, Borrelia, Chlamydia, and Mycobacterium, respectively. The pattern of hybridization between a 0.4-kb HSP70 probe and ehrlichial genomic DNA digested with various restriction enzymes is presented in Fig. 2. The hybridization result indicates that the ehrlichial chromosome contains a single copy of the HSP70 gene. Based on the sequence data, there were no EcoRI sites within the HSP70 gene, only one EcoRI site (at nucleotide position 1140), two Clal sites (at nucleotide positions 1014 and 1515), and two HindIII sites (at nucleotide positions 1437 and 1703) (Fig. 3). Since there is a Clal site in the 0.4-kb probe sequence (at nucleotide position 1014), there were two bands for Clal-digested DNA in the Southern blot result (Fig. 2). The results of restriction enzyme digestion and Southern blot analysis (Fig. 2) corresponded to the nucleotide sequence information.

Observation of relative mRNA levels of the ehrlichial HSP60 and HSP70 genes under heat stress. To examine the patterns of HSP60 and HSP70 mRNA levels under heat stress, a time course analysis was performed by using RT-PCR. The linearity of the RT-PCR assay was verified by using various amounts of target cDNA (HSP70 cDNA) (Fig. 5). Figure 5 shows that the intensities of the PCR products as measured by densitometry, when plotted against the amount of cDNA, yielded a linear relationship \( r = 0.99 \). A photograph of an ethidium bromide-agarose gel was obtained under optimal exposure conditions to avoid saturating strong bands while exposing weak bands. Additional PCR experiments performed with the target cDNA (16S rRNA) in the same manner showed similar results (data not shown). No PCR product was generated when RNA of uninfected P388D1 cells was used as the template (data not shown). For the 28-to-37°C temperature transition, levels of HSP60 mRNA increased 1.5-fold 1 h after the temperature shift, reached a peak (2.5-fold) at 6 h, and remained at a higher level (about 2-fold) at 12 h (Table 1 and Fig. 6A). The response of HSP70 mRNA was slightly slower than that of HSP60 mRNA. The HSP70 mRNA response started 1 h after the temperature shift (Table 1 and Fig. 6A). The response of HSP70 mRNA was slightly slower than that of HSP60 mRNA. The HSP70 mRNA response started 1 h after the temperature shift (Table 1 and Fig. 6A). The response of HSP70 mRNA was slightly slower than that of HSP60 mRNA. The HSP70 mRNA response started 1 h after the temperature shift (Table 1 and Fig. 6A). The response of HSP70 mRNA was slightly slower than that of HSP60 mRNA. The HSP70 mRNA response started 1 h after the temperature shift (Table 1 and Fig. 6A). The response of HSP70 mRNA was slightly slower than that of HSP60 mRNA. The HSP70 mRNA response started 1 h after the temperature shift (Table 1 and Fig. 6A).

**DISCUSSION**

This is the first report of HSP mRNA expression in ehrlichiae and rickettsiae. Although the physiological mechanisms of the heat shock response in prokaryotic cells are yet to be investigated, upregulation of the HSP level under stress is critical for survival under unfavorable circumstances. Regulation of the heat shock response in prokaryotic cells has been extensively investigated for E. coli. High levels of both GroEL and GroEL-like proteins are induced during heat shock. In addition, the expression of HSPs has been shown to be induced by various stressors, including osmotic shock, starvation, and nutrient deprivation. The induction of HSPs in response to stress is mediated by the heat shock transcription factor (HSF), which is activated by the binding of heat shock inducers to a specific DNA sequence in the HSP promoter region.

**FIG. 4.** Alignment of the E. senettii (ES) HSP70 protein sequence with that of E. coli (ECO) DnaK and Brucella (BRU), Borrelia (BOR), Salmonella (SAL), Chlamydia (CHL), and Mycobacterium (MYC) HSP70. A dot represents an amino acid identical to that of ehrlichial HSP70; a dash represents a gap introduced into the sequence.
and DnaK synthesis have protective roles for *E. coli* growth between 20 and 40°C. Our data demonstrated that HSP60 and HSP70 mRNA of *E. sennetsu* were induced in different patterns by thermal stress, which may occur in ehrlichial infection. In this study, both ehrlichial HSP70 and HSP60 (GroEL) mRNA expression levels increased after 1 to 6 h of a heat shock consisting of a temperature shift from 28 to 37°C. Higher levels remained after 12 h. This indicated that both HSP60 and HSP70 are important for ehrlichial adaptation to ideal growth conditions (37°C) when they are transmitted from the tick to the mammalian host. It is unclear how the induced HSPs enhance ehrlichial viability in vivo during growth at the core temperatures of the human body. It is possible that HSPs facilitate cell adhesion between the organisms and host cells or stabilize $\sigma^{32}$ for rapid growth under ideal conditions. McCarty and Walker (19) indicated that a DnaK mutant impairs *E. coli* growth only at temperatures above 39°C. Our results for ehrlichial HSP70 showed a pattern similar to that found in the *E. coli* DnaK study. Ehrlichial HSP70 mRNA increased more than HSP60 mRNA when the temperature was raised from 37 to 40°C. The level of HSP70 mRNA increased significantly at 40°C and remained more than twice the level at 37°C at 12 h after the transition. In contrast, the level of HSP60 mRNA increased less after 2 h at 40°C and returned to the basal level after 12 h. These results suggest that HSP70 may play a more active role than HSP60 in ehrlichial survival during the febrile stage (40°C) in patients.

The interaction between HSP60 and HSP70 plays a critical role in the heat shock response. For instance, the dissociation of the GroEL (HSP60)-DnaK (HSP70) complex in cytosol up-regulates HSP60 expression in *E. coli* (19). Binding of $\sigma^{32}$ at the $\sim 35$ region (heat shock promoter) is thought to upregulate both GroEL and DnaK (5, 9, 33), which regulate the heat shock response. Like the HSP70 genes of *E. coli* and *Chlamydia* (5, 9), the ehrlichial HSP70 gene had a $\sim 35$ region that is similar to the consensus $\sigma^{32}$ promoter. However, previous studies also showed that the interaction between HSP60 and HSP70 under stress varies among bacteria. As in *E. coli*, HSP70 acts as a negative modulator for HSP60 expression in *Haemophilus ducreyi* in response to heat shock (22). However, Mogk et al. (20) reported that, in stressed *Bacillus subtilis*, GroEL acted as the modulator of the heat shock response instead of HSP70. They observed that the overproduction of GroEL decreased the expression of DnaK and that decreased expression of GroEL activated the expression of DnaK. The present ehrlichial study produced results similar to those of the *B. subtilis* study (20). After 2 h of heat stress at 40°C, the level of HSP70 mRNA of *E. sennetsu* kept increasing while the level of HSP60 mRNA declined. Although the trend at the 37°C transition was less remarkable than the trend at the 40°C transition, the transition results showed that increased HSP60 mRNA accompanied a stabilized HSP70 mRNA level. Our results suggest that HSP60 and HSP70 may play different roles under normal growth conditions and under febrile conditions. To understand the interaction between these major bacterial HSPs will require further investigation.

The role of HSP70 in ehrlichial pathogenesis is still unclear. Based on studies of other bacteria, HSP70 is not only involved in protein synthesis as a chaperone but also associated with the function of the bacterial outer membrane protein (12, 14, 24). Recent investigations of *Haemophilus* spp., *Borrelia* spp., and *Chlamydia* spp. show that thermoinduced or cell surface HSP70 may facilitate bacterial growth and survival by enhancing the binding between bacterial surface components and the membrane receptors of host cells (12, 14, 22, 24). It is also has been reported that *Mycobacterium* HSP70 directly and rapidly induced cytokine mRNA production including interleukin-1a (IL-1a), IL-1b, IL-6, tumor necrosis factor alpha, and granulocyte-macrophage colony-stimulating factor mRNA in macrophages (25). Since the interaction of ehrlichiae with host cells influences proinflammatory cytokine mRNA expression (17, 18), the first isolation of ehrlichial HSP genes and the

* Results are from triplicate assays. Data with the same superscript are not significantly different.
determination of the mRNA levels of ehrlichial HSP genes will give us a better understanding of pathogenesis in ehrlichiosis, an emerging disease. Cloning ehrlichial HSP70 might provide an additional tool for the investigation of Ehrlichia spp. and the host interaction.

This is the first report on cloning, sequencing, and expression of the ehrlichial HSP70 gene. Based on E. sen netsu HSP70 amino acid sequence data, the ehrlichial HSP70 has 67, 63, 63, 62, 58, and 53% identity with HSP70 of Brucella, E. coli, Salmonella, Borrelia, Chlamydia, and Mycobacterium, respectively. The heat shock response and HSPs have been evolutionarily conserved. Therefore, when more data are available, a phylogenetic analysis of HSP70 may provide us another tool to investigate molecular evolution among prokaryotic cells. The system may serve as a model for studying mRNA expression and regulation of intracellular bacteria.
